7.	Annexure-III : Track plot for carnivores and mega herbivores (pressure impression pad)	21
8.	Annexure-IV : Format for recording camera trap capture data to obtain tiger numbers at the reserve level	22-24
9.	Annexure-V : Basic information on mark recapture	25-43
10.	Annexure-VI : Capture-recapture sampling data format using camera trapping (Mark software format)	44
11.	Annexure-VII : Data sheet for tiger, other animals and human signs encounter rates for Sundarbans	45-46
12.	Annexure-VIII : Encounter rate on line transects for Sundarbans	47
13.	Annexure-IX : Format for vegetation data for Sundarbans	48
14.	Annexure-X : Format for recording human disturbance for Sundarbans	49

A NOTE ON PHASE-IV MONITORING

(Continuous monitoring of tiger reserves / tiger source areas)

1. BACKGROUND

1.1 The Tiger Task Force constituted by the National Board for Wildlife (2005) has endorsed the revised methodology / approach propounded by the erstwhile Project Tiger Directorate (now the National Tiger Conservation Authority-NTCA) and the Wildlife Institute of India (WII) for country level estimation / monitoring of tiger / prey status and its habitat. The said approach, inter alia, comprises of the following:

- (a) Country level assessment of tiger, co-predators, prey and habitat in 17 tiger States once in every four years using the double sampling method having three phases (Phase-I: Spatial mapping and monitoring of tigers, prey and habitat; Phase-II: Assimilation of spatial and attribute data; and Phase-III: Estimating the population of tigers and its prey).
- (b) Intensive monitoring of tiger source populations in tiger reserves and protected areas in each tiger landscape complex (Phase-IV), and maintenance of a centralized photo-database of tigers at NTCA obtained from camera traps deployed across all tiger reserves.
- (c) Routine management-oriented monitoring, which, inter alia, comprises of regular monitoring of tiger signs at beat level, which can potentially be integrated with monitoring of law enforcement and patrolling.
- (d) Survey Design (for all tiger reserves except Sundarbans) for spatially explicit mark-recapture study involving research workers / scientists is at **Appendix-I**.

1.2 The above endorsement of the Tiger Task Force is being implemented and has also been reiterated in the guidelines issued by the NTCA (Technical Document: NTCA/01/07). In a country level meeting of Chief Wildlife Wardens / Field Directors held in May, 2011, it was decided to taken to implement the Phase-IV monitoring from

November, 2011. This was followed by a discussion with experts / NTCA members and a meeting with Chief Wildlife Wardens / Field Directors in October, 2011.

As per the decision taken, the minimum standards for the Phase IV protocols were:-

- (1) Camera trap density one pair per 4-5 sq.km.
- (2) Minimum trap nights of a 1000 per 100 sq.km. (i.e. 25 pairs of cameras in 100 sq.km. for 40 days)
- (3) Minimum area coverage of 400 sq.km.
- (4) Closure period of 40 to 60 days
- (5) Minimum of 20 spatial replicates of line transects each of a minimum of 2 km length (for the entire reserve)
- (6) Entire reserve needs to be sampled. *Each sampling occasion should cover minimum area of 400 sq.km (100 pairs of cameras) and in case of larger reserves, the area should be covered by dividing the area into 400 sq.km blocks and camera trapping should be done successively, within the closure period of 60 days.*
- (7) Closure period is 40 to 60 days, although the sampling could continue beyond this period, but truncation of the closure period could be done during analysis.
- (8) Two to four transects of 2km length for each beat to be walked thrice during each season. This protocol should be done for two seasons (summer and winter).

The protocol developed by NTCA addresses all of these minimum requirements of the Phase IV since it entails the entire tiger reserve with a camera density of a minimum of 3 per beat. The cameras will be operated for a long duration (several months), for closure the data could be truncated at any number of occasions as the biologist working with the TR desires. The objective of the NTCA exercise is to obtain a minimum number of tigers in a Tiger Reserve but also permits any biologist to generate data for any indepth statistical analysis including spatially explicit mark re-capture analysis using SPACECAP / DENSITY & DISTANCE for prey density estimates.

In brief, the Phase-IV protocol of NTCA contains six components:

- (a) Maintaining daily patrolling log

- (b) Carrying out the eight day protocol (Phase-I country level assessment) twice a year
- (c) Recording from PIP
- (d) Obtaining minimum tiger number using camera traps
- (e) Obtaining tiger numbers using camera traps (40-60 days closure period)
- (f) Obtaining minimum tiger numbers through DNA analysis from scats

The field managers are familiar with most of these components. Under Phase-IV monitoring, emphasis have been given on the use of camera traps at beat level for obtaining minimum tiger numbers, besides estimating prey density using DISTANCE from line transects. It must be borne in mind that for data analysis using camera trap data in a mark recapture framework as well as DISTANCE sampling, the 'detection probability' or 'probability of detecting animals' is important. Further, it is important to note that more animals in an area may not result in enhanced detection probability, since the latter is governed by terrain features, cover, visibility etc. However, more animals in an area may result in more detections on a line transect or more captures during a camera session.

The phrase 'detection probability' is used in line transects, whereas 'proportions of animals captured' is used in the context of camera traps. The 'proportion of capture' or 'capture probability' facilitates estimation of true population size. To illustrate the importance of a detection probability, a simple example is given below:

- 100 spotted deer were introduced in a known area
- 10 teams were sent for counting which gave a figure of 100 spotted deer
- The same area was traversed by a team of two persons six times resulting in a count of 62 spotted deer (mean)
- Here, the detection probability = $\hat{\beta} = 62/100 = 0.62$
- After a year, the area was again counted along the same trail resulting in a count of 90 spotted deer
- The population estimation is done as below:
 $90/0.62 = 145$ spotted deer

Thus a generic formula is given for population estimation:

$$\hat{N} = \hat{C} / \hat{P}$$

where, \hat{N} = population

\hat{C} = count / index

\hat{P} = probability of detection

In the above example, the initial figure of 100 spotted deer was known, which is not the situation under wild conditions. Further, two counts / indices can be compared only if we know the probability / estimate the probability of detection. Thus, both in camera trap as well as distance sampling, the analysis part requires estimation of the probability of detection / capture.

Quick Reference Guide

Phase IV involves monitoring of Tiger and its prey on annual basis at Tiger Reserve level, while Phase I to III is done at every 4 year interval for country level monitoring. The following needs to be kept in mind while planning the Phase IV:

Carnivore population estimation

- 1) Camera trap density one per 4-5 sq km***
- 2) Minimum trap nights of a 1000 per 100 sq km***
- 3) Minimum area coverage of 400 sq. km or whatever is the reserve size***
- 4) Closure period of 40 to 60 days***

Trap night are number of days of operation multiplied by number of pair of cameras. Closure period is time frame within which animal movement in and out of study area, birth and death are going to have no or negligible effect.

2. PHASE-IV MANAGEMENT-ORIENTED MONITORING

I. For all tiger reserves except Sundarbans

Part-A Maintaining daily patrolling log in patrolling camp / chowki registers

While on regular or targeted patrolling duties the personnel shall record the following information:

- 1) Each patrolling team shall be equipped with a GPS unit and a digital camera besides the regular equipment (e.g. firearms, wireless, torch, etc).
- 2) The date, time and GPS coordinates of the beginning of the patrol recorded.
- 3) Preferably the GPS unit shall be switched on throughout the patrol in a track log mode. However, due to constraints of technical knowhow or other issues if this is not possible then a GPS coordinate recorded and written down in the record form every 30 min or at major deviations from a straight line path.
- 4) The total number of persons on the patrol are recorded along with number of armed personnel and type of arms. The mode of patrol is also recorded, e.g. on foot, bicycle, motorcycle, 4WD, elephant, boat, etc.
- 5) A record of all illegal activities is entered in the data sheet along with time, date and coordinate stamp. A photograph is also taken of the site with a time date stamp.
- 6) A record of signs and sightings or highly endangered species while on Patrol is also maintained by entering the GPS coordinate, date and time of the sighting /sign as well as recording a digital picture of the same if possible.
- 7) After the end of the Patrol, the GPS track log is either downloaded onto a computer (in MStrIPES program if applicable) or the datasheet with the recorded information deposited at the Range Head Quarters. Data formats for recording Patrol data are provided in **Annexure-I**.

Part-B Carrying out the 8 day protocol of Phase-I twice a year

The entire tiger reserve would be covered at the beat level, by considering the latter as a sampling unit, as done in Phase-I of the country level assessment by following the standardized eight day protocol. This would involve beat wise collection of data (in the standardized formats) twice a year relating to tiger / carnivore signs survey, ungulate, encounter rates, habitat status, human presence and pellet / dung counts. Based on such data, beat level maps indicating the spatial presence / relative abundance (index) of prey / predators species should be prepared in the GIS domain for record.

- (i) Beat-wise collection of data in the standardized formats of Phase-I country level assessment process.
- (ii) Length of the transect (2 km), number of spatial replicates (2-4 per beat) and temporal replicates (minimum of 3 walks). Each transect should be spaced at least 1.5 km within and between beats.
- (iii) The data collection should be done twice a year (summer and winter).
- (iv) The line transect data should be analysed using the "DISTANCE" software for prey density (not for encounter as done in the country level assessment).
- (v) The format for collecting line transect data to facilitate analysis using "DISTANCE" software and the basics of DISTANCE sampling using line transects are provided at **Annexure-II**.

Part-C Recording data from 'pressure impression pads' (PIP)

As a part of intensive monitoring of source populations of tigers, data will be recorded from pressure impression pads (PIP's, track plots) in every beat.

- A minimum of 5 PIPs will be permanently maintained in each beat. The dimension of the PIP shall not be less than 6m in length the width of the PIP should equal the foot path, jungle trail or dry nullaha's width on which the PIP is made. GPS coordinates of all PIP's need to be recorded.

- The location of the PIPs within the beat should be such that they maximize the possibility of recording carnivore tracks. Minimum distance between any 2 PIPs should be more than 1.5km.
- The PIPs should be cleaned of debris, leaf litter, gravel and covered with fine dust of about 0.5cm depth. After preparing the PIP, data should be recorded the next morning and the PIP cleared of all tracks. The PIPs should be sampled thrice every month during summer and winter. In case a prepared PIP is disturbed due to rain, traffic etc. then it should be set again before data is collected. The topography and forest type should be recorded for each PIP.
- Trails of all carnivore and mega herbivores species should be recorded e.g. tiger one track set, leopard two track sets, several dhole track sets (as it may not be possible to identify individual track sets due to many tracks by a passing dhole pack), one small cat track (as species level identification may not be possible).
- It is important to note that a track set is constituted by one to many pugmarks made by a single animal traversing the track plot (PIP). One need not identify the gender or individual animal (tiger), but if this information is known, it should be entered in the remarks column. If there are more than one track sets of "same" animal eg. a tiger moving up and down the trail several times, they should be recorded as separate track sets. Data sheet for recording are provided in **Annexure-III**.

Part-D Obtaining the minimum number of tigers in the tiger reserve

- (i) Three pairs of camera traps to be deployed per beat.
- (ii) The photo captures obtained from camera trapping should be analysed for fixing individual IDs of tigers.
- (iii) A digital camera trap tiger photo database should be prepared for the reserve with location ID, Date and Time Stamps.
- (iv) The minimum number of tigers should be ascertained based on individual camera photo traps of tigers.
- (v) Details of new captures / missing tigers should be recorded.
- (vi) The format for recording the camera trap capture data is at **Annexure-IV**.

Part-E Obtaining the tiger numbers for the reserve using camera traps in a mark recapture framework

- (i) The camera traps deployed in beats (as indicated in Part-B) should be left open during winter months for a period of 40-60 days (depending on the areas).
- (ii) A summary record of photo captures should be prepared for analyzing the data to obtain the tiger number for the reserve using "CAPTURE" software.
- (iii) The analysis of the data needs to be done in collaboration with a technical expert / scientist conversant with the mark recapture process / analysis.
- (iv) The period of leaving the camera traps open (closure period) is important owing to the fundamental assumption of "population closure" (no deaths / births / immigrations / emigrations in the population). Leaving the cameras open for longer duration may lead to over estimation.
- (v) The format for summary record of camera captures and the basics of mark recapture process using camera traps are provided at **Annexures-V & VI**.
- (vi) The analysis of capture data between years (using open population models) should also be done in collaboration with technical experts / scientists/ WII.

Part-F Using scats for DNA analysis to obtain the minimum tiger numbers in reserves where camera trapping is not possible

- (i) Collection of tiger scat samples: a) Use disposable surgical gloves to handle scat samples, b) for each scat a new set of gloves should be used to avoid cross contamination, used gloves should be discarded in an environmentally friendly way c) about 20 gms of fresh scat sample should be taken and stored in a vial/tube containing buffer & / or 70% alcohol. Tubes should be prepared in duplicate with GPS coordinates and date clearly recorded on the tube (alcohol erases permanent marking pens).
- (ii) Obtaining the minimum number of tigers in the area through DNA analysis of tiger scats involving an institution having the domain expertise.

II. For Sundarbans Tiger Reserve

Part-A Maintaining daily patrolling log

The data collection would be similar to other tiger reserve. The GPS should be used in boat / canoe to give the track log for the patrol route.

Part-B Carrying out the 8 day protocol of Phase-I

The data collection needs to be done twice a year in the formats provided at **Annexures-VII, VIII, IX and X.**

(The relationship between signage and density would enable tiger status assessment from this data set).

SURVEY DESIGN (For all tiger reserves except Sundarbans) for spatially explicit mark-recapture study involving research workers / scientists

Minimum Standards for monitoring tiger source populations were:

Sampling area: Minimum area of 400 km² or entire Tiger Reserve, if area is smaller than 400 km².

(i) Tiger monitoring by camera trap sampling:

Camera density = 25 double-sided cameras per 100 km².

Sampling effort = 1000 trap nights / 100 km².

Closure period = 40-60 days

NOTE: The period of leaving the camera traps open (closure period) is important owing to the fundamental assumption of "population closure" (no deaths / births / immigrations / emigrations in the population). Leaving the cameras open for longer duration may lead to gross over estimation.

(ii) Prey monitoring by line transect sampling:

1) Straight or near straight line transects will be laid in each beat. Number of transects will depend on size of each beat, minimum 2 transects of 2km each will be laid per beat.

2) Each transect will be walked 3 times in a season and will be carried out twice once for winter and once for summer.

3) Total effort should not be less than 100 km or 40 sightings of major prey species on transects (for the entire reserve).

DESIGN OF SURVEYS ANALYSES OF DATA

- (i) The survey design and analysis of these data needs to be done in collaboration with a technical expert / scientist conversant with the advanced open and closed model mark-recapture and advanced distance sampling methodologies.
- (ii) The format for recording camera capture data and the basic ideas of the mark-recapture process using camera traps are provided at **Annexures-V & VI** and in published scientific literature.

Data Sheet-6 Patrol Form

Name of Guard: Date: Forest Division... .. Range:
 Beat: No. of Persons on Patrol: Armed... .. Unarmed... ..
 Patrol Type: General Duties, Investigations, Surveillance, Others Patrol Method: Foot, Jeep, Motorbike, Bicycle, Elephant and Others

Data	Time	Lat			Long			Place	Animal species seen	Group size seen	Illegal Activities				Animal Mortality Records							
		Deg	Min	Sec	Deg	Min	Sec				Type	Time elapsed	Details	Action taken	Species	Gender (M/F/Un)	Age (Y/Ad/Un)	Carcass state	Cause of death	Samples taken		

M - Male, F - Female, Un - Unknown, Y - Young, Ad - Adult.

Annexure-II

Field formats for data collection in distance sampling

I. Line Transect Data Sheet for monitoring of ungulate population by DISTANCE sampling:

Observer name: Start time: Date:
 End time: ID no. of line transect: Total length: km
 TR / Forest division: Range: Beat:
 Weather condition: Cloudy/Clear sky
 Beginning GPS Lat:N; Long:E
 End GPS Lat:N; Long:E

Sighting No	Time	Species*	Total Nos. (Adults & Young)	Young	Sighting Distance	Compass Bearing	Forest Type	Terrain Type	Remarks
1									
2									
3									
4									
5									
6									
7									
8									

*Species that need to be recorded on the transect: chital, sambar, nilgai, gaur, barking deer, elephant, rhino, wild buffalo, swamp deer, hog deer, chowsingha, blackbuck, chinkara, wild pig, langur, peafowl, hare, cattle (live stock), and other mammalian species seen.

II. Location of transects in relation to Vegetation and Terrain features

Transect No.	Total length (km)	Name	Bearing	GPS location		Vegetation type	Terrain category
				Start	End		
T1							
T2							
T3							
T4							
T5							
T6							
T7							

Annexure-II
(Basic Information)

**Assessment of prey at beat level using line transects and
analyzing the data with DISTANCE Software**

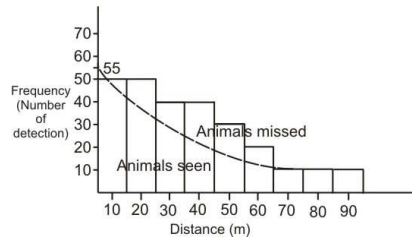

- (i) The use of line transect in estimation of prey density is known as 'line transect sampling'. This technique of abundance estimation is included under 'distance sampling'.
- (ii) It provides a direct estimate of density, provided its assumptions are met.
- (iii) It also accounts for the probability of detection.
- (iv) In 'Distance Sampling', the fact that the 'probability of detection decreases with increasing distance from the observer' is modelled by developing a function, which is used to estimate the 'probability of detection' ($\hat{\beta}$). The density (\hat{D}) is estimated as below:

$$\hat{D} = \frac{n}{\alpha \hat{\beta}}$$

where, n = total number of detections
 α = total area sampled

(v) The observer travels along a line of length 'L', located randomly in the study area, and counts all the animals which are seen. There is no assumption that all animals are counted, and the counts are assumed to be incomplete. More often, a maximum observation distance 'w', which is perpendicular to the transect line on each side, is established. Beyond this distance, no count is made. In some cases, counting of all animals is done without establishing a distance.

(vi) Let us consider the common approach of establishing the 'maximum observation distance' (w). Here, it is important to estimate the 'detection probability' or the proportion of animals that are actually seen (β). This is required to correct the actual counts.

(Hypothetical from the transect line histogram plot of the number of detections against the distance from the transect line, with a smooth function fit.)

(vii) If the number of detections are plotted against distance from the transect line, a smaller number of detections are seen as the distance increases. The detection function to the observed distances is fitted to estimate the detection probability $\hat{\beta}$:-

$$\hat{\beta} = \frac{\text{Area under the curve}}{\text{Total area}} = \frac{3500}{4950} = 0.70$$

(viii) Once the detection probability ($\hat{\beta}$) is computed, animal abundance in the survey area can be calculated, as in the case of the strip sampling, using the canonical estimator as before:

$$\hat{N} = \frac{An}{2wL\hat{\beta}}$$

(ix) For animal density (\hat{D}), the abundance needs to be divided by area, resulting in:

$$\hat{D} = \frac{n}{2wL\hat{\beta}}$$

(x) The salient features of this estimation technique are as below:-

- From the transect line, the perpendicular distances (x) to each detected animal of interest are computed by measuring the detecting angles ' θ ' and detection distances 'r'.
- This computation is done as $x = r \sin \theta$.
- Imagine a situation where 'k' transect lines have been laid

in some randomized design, having lengths l_1, \dots, l_k , with a total length 'L'.

- d. Further, suppose that 'n' animals are seen at perpendicular distances x_1, x_2, \dots, x_n , and animals beyond a distance (w) from the transect (truncation distance) are not taken into account.
- e. In the above situation, the area surveyed (a) is given by :
 $a = 2wL$.
- f. Say 'n' animals are seen/detected within this area.
- g. Estimation of animal density (D) is given by:

$$\hat{D} = \frac{n}{cwL\hat{P}_a}$$

where, P_a = probability of detection of a randomly chosen animal within the area surveyed;

\hat{P}_a = estimate of P_a

- h. Thus, it becomes necessary to give a framework to estimate P_a . In this context, the 'detection function' 'g(x)' is defined as the probability of an animal at distance x from the transect line being detected, given that x is between w and 0 (i.e. $0 \leq x \leq w$). Further, it is also assumed that animals on the transect are certainly detected (i.e. $g(0) = 1$).
- i. A new parameter ' μ ' is now defined, which is known as the 'effective strip (half) width'. It is the distance from the transect 'for which as many objects as are detected beyond μ as are missed within μ '.
(Defining a detection function $g(x)$, where $g(0) = 1$; μ = the effective strip width).
- j. If the detection function $g(x)$ is plotted against perpendicular distances 'w' as a histogram, a model for $g(x)$ needs to be specified, and fitted to the distance data.

P_a is related to μ . If the definition for $\mu = \int_0^w g(x)dx$, then $P_a = \mu/w$.

$$\text{Thus, } \hat{D} = \frac{n}{a\hat{P}_a} = \frac{n}{2wL\hat{\mu}/w} = \frac{n}{2\hat{\mu}L}$$

- k. Now $\mu(\text{hat})$, an estimate of μ is required. For this another function known as the 'probability density function' (pdf) of perpendicular distances $f(x)$ to detected animals is used. This is the rescaled detection function $g(x)$ for integrating into unity; i.e. $f(x) = g(x)/\mu$. Since it is assumed that $g(0) = 1$, hence $f(0) = 1/\mu$.

$$\text{Thus, } \hat{D} = \frac{n}{2\mu L} = \frac{n\hat{f}(0)}{2L}$$

[Fitting the probability density function (pdf) to the data. The area under this function is 1].

$f(x)$ is the pdf of perpendicular distance p frequencies, plotted on a histogram of perpendicular distance frequencies. These are scaled so that the area of the histogram is 1. By definition, the area below the curve is unity (1). The two shaded areas in the above curve are equal in size, hence the area of the rectangle, $\mu f(0)$ is also unity, resulting in $\mu = 1/f(0)$.

- l. Thus the pdf of perpendicular distances are modeled, and

the fitted function is evaluated at $x=0$. The DISTANCE Software address this standard statistical issue. A parametric 'key' function is selected. However, if the fit provided by it is not adequate, adjustment are done using polynomial or cosine series, till the fit is judged satisfactory by one or more criteria.

m. Usually, the data are grouped into distance categories before analysis and such grouped data is fitted using standard likelihood methods from the multinomial data.

(xi) The distance software calculates variance and confidence in interval inherently and also besides addressing the estimation of cluster size.

(xii) The data from a line transects includes: (a) number of individual animals / number of individual animals in a cluster, (b) the perpendicular distance of the animal / centre of the cluster from the transect, (c) name / identity of the transect line where count was made / detected, (d) total length of the transect line.

(xiii) The transects should be made in all the beats (at least two line transects of 2 km each per beat).

(xiv) The transect lines may be straight lines or conforming to a continuous shape leading to the starting point. The transects should be randomly laid, separated by at least a distance of 2 to 3 km. and physically marked using GPS for replication.

(xv) The total walks on a transect (total effort) is computed by adding all the walks done on a transects, and totaling up such walks on all the transects laid in the area.

(xvi) For low density areas, more efforts may be required on the transects.

(xvii) Laser range finders and compass should be used for measuring distance and angle respectively.

Assumptions in line transect sampling:

The critical assumptions in line transect sampling, which should be met for a reliable density / abundance estimation are as below:

A. Random location of transect lines with respect to distribution of animals:

This assumption helps in estimating the detection function from the observed distribution of perpendicular distances, leading to the average probability of detection (p). To ensure this assumption, the transect lines should be laid randomly, causing minimum disturbance to the habitat.

B. Detection of animals with certainty on the transect line :

This assumption is fundamental for deriving the density estimator, wherein detection of all objects at 0 perpendicular distance are assumed (i.e. $g(0) = 1$). The density would be under estimated if objects / animals falling on the transects are missed, since bias is a simple function of $g(0)$. Thus, by missing 15% of the animals on the transect line, the density estimate on an average would be less by 15%.

C. Detection of animals at their initial location:

This assumption can be easily met for stationary objects like plants or dung piles of wild animals, but it is difficult to meet for moving animals. It has been pointed out that movement does not create much problem provided it is not in response to the observer. Further, comparatively faster movement of observers also reduces the problem. However, the observers should move as silently as possible to avoid evasive movement of the animals before detection, while trying to detect them. A considerable evasive movement of animals would lead to under estimation.

D. Exact measurements are made:

Proper field measurements are essential to record reliable measurements. Erroneous recordings relating to animals on transect line from a distance makes analysis difficult.

Apart from the above, the other assumptions include :

- (a) Detections are independent events.
- (b) Animals should not be counted twice on the same line.

Hypothetical example of distance sampling:

```
Effort      : 126.0000
# samples   : 42
Width      : 256.0000
Left       : 0.0000000
# observations: 447
```

Cell i	Cut Points	Observed Values	Expected Values	Chi-square Values	
1	0.000	44.2	309	308.43	0.001
2	44.2	88.3	93	93.78	0.007
3	88.3	145.	34	34.07	0.000
4	145.	220.	11	10.67	0.011
5	220.	240.	0	0.05	0.054
6	240.	256.	0	0.01	0.007

Total Chi-square value = 0.08 Degrees of Freedom = 2.00

Probability of a greater chi-square value, P = 0.96098

The program has limited capability for pooling. The user should judge the necessity for pooling and if necessary, do pooling by hand.

There is a need for some pooling to achieve a reliable chi-square test. However, the pooling algorithm built into this program would result in no degrees of freedom left. Therefore pooling is left to the user.

One or more expected values is < 1.
Try pooling some cells by hand to obtain a more reliable test.

Annexure-IV

Format for recording camera trap capture data to obtain tiger numbers at the reserve level

- 1) Place double-sided camera traps at the best locations within a beat to photograph tigers.
- 2) The distance between camera traps within and between beats should be over 1.5 km.
- 3) A minimum of 3 camera traps (consisting of double sided cameras) per beat should be deployed. The number of camera trap will increase as the size of the beat increases, keeping the strategy of one pair of camera traps for 4 sq.km. area (2 km x 2 km).
- 4) The GPS coordinates of each camera location and the dates of deployment should be recorded as given below:

Camera Trap Station ID	Degree, Min, Sec North	Degree, Min, Sec South	Dates deployed	Dates not operating
1 – main Rd nalla				
2- River Junct				
3- temple jct				
4-.....				

5) Format for daily monitoring of camera traps (beat-wise)

Date	Camera Unit	Camera Trap Station 1			Camera Trap Station 2			Camera Trap Station 3			Remarks*
		Tiger	Leopard	Other	Tiger	Leopard	Other	Tiger	Leopard	Other	
	A – Right Side Camera

* Non-functioning of camera traps or missing of tiger capture, etc. to be recorded in the Remark column.

- 6) Photographs of tigers, leopards and all mammal species should be downloaded and saved as folders for each species. Each photograph should have a time and date stamp recorded digitally, the camera trap station identity stored in the file name. An appropriate format is to have a species folder e.g. tiger, sub folder for camera trap station id, within which photographs of each of the cameras (from the double sided camera traps) is stored as separate folders. A CD with the above data (points 4, & 5) should be sent to NTCA every 2 months.
- 7) All Photographs of tigers and leopards should be printed and compared visually based on their stripe and spot patterns to identify individuals. In case of >15 tigers/leopard captures the need of software assisted identification may become essential.
- 8) For estimation of the tiger/leopard population after individual identification using closed capture estimators the data needs to be arranged in the format given below:

Trap Occasion (Day)

Tiger / Leopard ID	Day 1	Day 2	Day 3	Day 35	Day 48....
T-1							
T-2							
T-3							
T-4-.....							

Annexure-V

(Basic information on mark recapture)

Assessment of tiger population at beat level using photographic mark-recapture camera trapping while analyzing the data with an appropriate softwares like MARK, CAPTURE and CARE. This should result in the preparation of a reserve-level photo-capture database of individual tigers, to be shared with the Chief Wildlife Warden / NTCA / WII.

(I) The capture–recapture methodology is largely derived from the classical Peterson-Lincoln Estimator which is highlighted below:

Peterson Estimate (Lincoln Index)

The mark-recapture methods based on Peterson Estimate constitute the most important pseudo-sample methods. A large number of variations of this basic method have been evolved, which have been further complicated since the technique is simultaneously utilised to measure movement or mortality.

Here the sample of a population is marked after it is caught and then released; subsequently, samples are again taken from the population after recapturing and the proportion of marked individuals are recorded. Using the proportion of marked individuals in the subsequent samples, the total population is estimated. The capture-recapture sampling facilitate estimation of the 'proportion' of animals captured which facilitates estimation of true population size.

The simplest form of the mark-recapture estimator is the Lincoln-Peterson estimator; this is known variously as 'Peterson index', 'Lincoln index' or 'the Peterson estimate'. This method gives an estimate of actual numbers and hence it is a sample census rather than an index. Peterson, in 1896, described this method for fish populations; however it was first applied for wildlife in 1930 by F.C. Lincoln, for populations of waterfowl.

The model can be derived from the ratio:
$$\frac{M}{\hat{N}} = \frac{m}{n}$$

where, M= total number of individuals marked and released during the first capture period;
 \hat{N} = estimated population size (unknown);
 n = total sample taken during the second capture period;
 m = number of individuals captured in the second capture which were marked.

The above ratio can be rewritten as an estimator:

$$\hat{N} = \frac{Mn}{m}$$

Theoretically this is a very elegant and simple method and can be applied to any vertebrate which can be captured, viz. from fish to cats. However, it is time consuming, laborious and costly and becomes impractical for large areas. Apart from this, several critical assumptions of this method act as constraints:—

1. Each animal has an equal chance of being captured.
2. The behaviour of animals is not influenced by marking.
3. No marks are lost.
4. The individuals which are marked mix randomly in the population after release.
5. There are no immigrations or births in the area under study between the first and second trapping seasons.
6. There is no emigration or differential mortality between the marked and unmarked members of the population.
7. The population is closed; if mortality occurs, then the estimate of N is valid for the initial size of the population. If recruitment occurs then N is valid for the time of recapture.
8. The time spent in sampling is small relative to the inter-sampling period.

The model assumptions can be re-written concisely as follows:

Assumption 1. A well defined population of animals having N individuals exists.

- Assumption 2. M of these individuals are marked.
- Assumption 3. There exists a sample of n 'observations' of animals from the population, having x 'observations' marked animals.
- Assumption 4. The average probability \bar{p}_m of observing an animal that is marked is equal to \bar{p}_u which is the average probability of observing an unmarked animal.
i.e. $\bar{p}_m = \bar{p}_u$

The formula $\hat{N} = \frac{nM}{m}$ can be used satisfactorily with appropriate assumptions.

Use of Lincoln-Petersen Sample Estimator in camera trapping of tigers

The sample periods can be aggregated into two groups – viz. in a session of 30 days, the first 15 days can be denoted as 'occasion-1' and the next fortnight as 'occasion-2'.

In general, for photo trapping of tigers, the camera traps are set in the study area, covering the animals so that the tigers in the area can encounter the traps at least once (preventing 'holes' so that tigers are not missed). The traps are set for several days in succession, and each day is considered as a 'sample period'. In large areas, the traps can be 'rotated' over the area as per a prescribed scheme, and the data collected over the number of days taken to cover the entire area defines the sampling period.

The camera trap data is summarised in 'capture-history' data sheets, consisting of rows of 'i' and 'o', which indicate the periods when an animal was camera trapped. Thus, a history of '100101', indicates that a tiger was trapped in periods 1, 4 and 6 of a study having 6 periods.

Example

m_1 = number of tigers, with known identity, trapped on occasion 1

m_2 = number of tigers trapped and released on occasion 2

m = number of tigers recaptured in period 2 (i.e. trapped at both occasions 1 and 2)

1. The unknown quantity of interest (total number of tigers in the sampled population) is defined as 'N'.
2. The model parameters are then defined as:
 $p_i =$ probability of a tiger exposed to sampling efforts in the sampled area is trapped on occasion i ($i = 1, 2$)
3. $p = 1 - (1 - p_1)(1 - p_2)$ = the probability that a tiger, from the total number of tigers in the sampled population N , is trapped at least once during the study.
4. The 'detection probabilities' for the two sampling periods are estimated, by ascertaining the proportion of tigers which were trapped in one occasion are also trapped in the other occasion. Since the population is "closed", it can be said that the tigers caught during occasion 1 are also present during occasion 2. Thus by "conditioning" tigers trapped in occasion 2, and ascertaining the number of these tigers which were also trapped during occasion 1, p_1 and p_2 can be estimated:

$$\hat{p}_1 = \frac{m}{n_2}, \quad \hat{p}_2 = \frac{m}{n_1}$$

$$\hat{p} = 1 - (1 - \hat{p}_1)(1 - \hat{p}_2)$$

The general equation for estimating abundance is:

$$\hat{N} = \frac{C}{\hat{p}},$$

where, \hat{N} = estimate of abundance N (true number of tigers)

C = Number of tigers counted

p = estimate of capture probability 'p' (probability that a tiger exposed to sampling efforts in the sampled area is captured on occasion i ($i=1, 2$))

For period 1, the following estimator is obtained:

$$\hat{N} = \frac{n_1}{\hat{p}_1} = \frac{n_1}{m/m_2} = \frac{n_1 n_2}{m}$$

For period 2, the following estimator is obtained:

$$\hat{N} = \frac{n_2}{\hat{p}_2} = \frac{n_2}{m/m_1} = \frac{n_1 n_2}{m}$$

The assumptions of the Lincoln-Peterson model are again stated below:-

1. The population is a 'closed' one.
2. It is likely that all animals are equally captured in each sample (equal probability of capture).
3. The marks are not overlooked, gained or lost.

A short interval between samples can meet the first assumption. The second assumption is often relaxed, while the last one can be met with proper marking techniques.

Example of Lincoln-Peterson estimate

(camera trapping exercise)

50 camera traps are placed in a tiger habitat along trails, and for two consecutive nights photographs are taken, resulting in the following data:

$n_1 = 10$ tigers camera trapped during the first night

$n_2 = 8$ tigers camera trapped during the second night

$m = 2$ tigers camera were photographed on both the nights

Estimation of capture probabilities and abundance

Capture probabilities of each night (sampling occasion) and for both nights (combined) are calculated as below:

$$p_1 = \frac{2}{8} = 0.25$$

$$p_2 = \frac{2}{10} = 0.20$$

$$\hat{p} = 1 - (1 - p_1)(1 - p_2)$$

$$\begin{aligned} \text{i.e. } \hat{p} &= 1 - (1 - 0.25)(1 - 0.20) \\ &= 1 - (0.75)(0.80) \\ &= 0.40 \end{aligned}$$

Using the Chapman estimator for abundance:

$$\hat{N}_c = \frac{(n_1 + 1)(n_2 + 1)}{(m_2 + 1)} - 1$$

$$= \frac{(10 + 1)(8 + 1)}{(2 + 1)} - 1$$

$$= 32.$$

The Variance and Standard Error for the estimate are as below:

$$\text{Var}(\hat{N}_c) = \frac{(10 + 1)(8 + 1)(10 - 2)(8 - 2)}{(2 + 1)^2(2 + 2)}$$

$$= \frac{(11)(9)(8)(6)}{(3)^2(4)} = \frac{4752}{36} = 132$$

$$= \hat{SE}(\hat{N}) = \sqrt{132} = 11.49$$

Thus, the estimated number of tigers in the sampled area is 32.

An approximate 95% confidence interval for this estimate is given by:

$$\hat{N} \pm 1.96 SE(\hat{N}) = 32 \pm 22.52 = (54.52, 9.48)$$

The above estimate is not precise and is highly uncertain, perhaps owing to small sample size in studies of elusive animals like the tiger.

(II) Broadly, the mark recapture methods have been categorised on the basis of population 'closure' as below:-

- (1) Closed Population Models – Where the total number of individuals in a population does not change due to birth, deaths, immigration or emigration. There are no 'gains' or 'losses' in the population between sampling occasions. Hence, these are most suitable for short-time period estimators like abundance estimation.
- (2) Open Population Models – Where the population is changing during the study due to births, deaths, immigration or emigration. These gains or losses or both occur between the sampling periods. The time interval between sampling occasions is longer. These models provide scope for estimation of abundance, survival rate and recruitment.

(III) In the Indian context, both models are applicable. The closed population models are good for abundance estimation of tigers and its prey in the country level estimation was carried out after every four years. The open population models are suitable for long term studies (e.g. Phase IV of the new methodology at source sites for monitoring tiger and its prey). In this chapter, the focus would be on the 'closed population model' owing to their relevance in the context of tiger estimation.

Capture-Recapture Models for closed population

Capture-Recapture Data

In the capture-recapture approach, the capture history of the individual animal is maintained as a series of "non-captures" (0's) and "captures" (1's).

Hypothetical Individual Capture history of 10 tigers with four capture (camera trap) occasions

Tiger	Occasion 1	Occasion 2	Occasion 3	Occasion 4
1	1	1	1	1
2	1	1	0	0
3	1	1	1	0
4	1	1	1	1
5	0	1	0	0
6	0	0	1	0
7	0	0	0	1
8	0	0	0	1
9	0	0	1	0
10	0	1	0	0

The first tiger has a capture record of (1111), and was photo captured on all four occasions. The second tiger, having a photo capture record of (1100), was captured on occasions 1 and 2. Rest of the capture history data can be interpreted similarly. Since the capture-recapture data involving a number of animals becomes large, it is usually represented in the form of summary statistics for statistical analysis:-

- k = number of capture occasions;
 - n_j = number of animals captured on the j^{th} occasion ($j=1, \dots, k$);
 - u_j = number of unmarked animals captured on the j^{th} occasion ($j=1, \dots, k$);
 - m_j = number of marked animals captured on the j^{th} occasion ($j=1, \dots, k$);
 - M_j = number of distinct animals captured before the j^{th} occasion ($j=1, \dots, k$);
- ($M_1=0$, and M_{k+1} is the total number of distinct animal captured in the exercise);
- f_j = number of animals captured exactly j times ($j=1, \dots, k$);

The statistics pertaining to the hypothetical capture history data is provided as a summary below:

Summary Statistics for the Capture history of tigers

J	n_j	m_j	u_j	M_j	f_{1j}
1	4	0	4	0	6
2	6	4	2	4	1
3	5	3	2	6	1
4	4	2	2	8	2
				10 ($M_5=10$)	
TOTAL	19	9	10		10

Description of the statistics:

- n_j = column sum for the j^{th} occasion (column) in the capture data (history matrix), with (n_1, n_2, \dots, n_4) .
- u_j = first captures out of n_j animals, with $(u_1, u_2, \dots, u_4) = (4, 2, 2, 2)$.
- m_j = recaptures out of n_j animals, with $(m_1, m_2, \dots, m_4) = (0, 4, 3, 2)$.
($u_j + m_j = n_j$ i.e. 19)
- M_j = cumulative number of first recaptures on the first $j-1$ occasions, thus $M_j = u_1 + u_2 + \dots + u_{j-1}$ and $(M_1, M_2, \dots, M_5) = (0, 4, 6, 8, 10)$; i.e. there is a progressive increase of marked animals in the population from $M_1 = 0$ to $M_5 = 10$.

The capture frequency of an animal is denoted by its row sum. Thus (f_1, f_2, \dots, f_k) denote the frequency counts of all the animals which were capture $(6, 1, 1, 2)$. Thus, 6 tigers were photo captured once, one tiger photo captured twice, one tiger photo captured thrice and two on all the four occasions.

The number of animals which are never captured is represented by ' f_0 ', so that $f_1 + f_2 + \dots, f_k = M$ and $f_0 + f_1 + \dots, f_k = N$. Thus estimation of population size ' N ' becomes equivalent to estimation of f_0 , the number of missing animals ($N = M_{t+1} + f_0$).

(IV) There are a number of models to address different sources of variation in capture probabilities, which are available in the software (CAPTURE):

1. M_o : equal probability of capture model
2. M_h : Heterogeneity Model
3. M_{bh} : Behaviour-heterogeneity Model
4. M_t : Time Variation (Schnabel) Model
5. M_{th} : Time-Heterogeneity Model
6. M_{tb} : Time-behavioural Response Model
7. M_h : Heterogeneity Model

(V) Issues relating to survey design (for camera trapping of tigers)

Some general considerations are as below:

1. The sampling time in camera trapping of tigers should be 'short' vis-à-vis the tiger populations turn over for meeting the assumptions relating to 'close models'. It has been stated that four to six weeks of sampling through camera trapping may be needed which may be stretched to eight to twelve weeks. Experience in general indicates that a period of six to eight weeks of sampling may be required.
2. The space should provide scope for every animal in the study area to have some chance of being captured.
3. The camera traps should be adequately spread through out the study area and should be checked each day during the sampling period to get a good capture history data.
4. The study area may be divided into a number of potential sampling units, whose size should be just sufficient to set up a single camera trap. Each sampling unit can be considered as a 'grid cell' which can be randomly selected to place camera traps at sites which are promising. In the following day, the camera can be moved to other such sites in the grid cell and the process can be repeated between five to thirty days to get a standard capture history data.
5. If the area is difficult or the number of camera traps are not adequate, then smaller portions of the area can be covered (block-wise) for camera trapping for a short period of time before moving successively to other portions. The total number of days used for camera trapping to cover the entire area (all

blocks) is denoted as sample occasion 1. The procedure is repeated to get the capture occasion 2.

The other considerations in camera trapping of tigers include choice of the equipment (camera and the tripping device), choice of sites to set up the traps, spacing of traps and a standard data collection protocol. The tigers are identified visually from photographs using their unique stripe patterns:

Hiby et. al. have used a three dimensional model to match images of living tigers and tiger skins.

The identified individual tigers are numbered and every capture of an individual tiger is assigned to a particular secondary sampling occasions.

The capture history of individual tigers consist from the database in the standard history matrix and are analysed through a suitable computer program CAPTURE or MARK. During analysis, the results are checked to ascertain the violation / non-violation of the closure assumption and finally the statistical tests 'between models' is done to indicate the best fitting model vis-à-vis the data, from which the parameters are obtained. Since tigers are territorial, models which address heterogeneous capture probabilities (like M_h) should be used for tigers.

Program version of 16 May 1995 9-Dec-2010

rg2

Population estimate under individual heterogeneity in capture probabilities.

See model M(h) of Chao (1988).

Group 1

Number of trapping occasions was 6
Number of animals captured, M(t+1), was 10
Total number of captures, n., was 30

Frequencies of capture, f(i)
i= 1 2 3 4 5 6
f(i)= 0 2 6 2 0 0

Average probability of capture = 0.5000

Population estimate is 10 with standard error 0.0000

Approximate 95 percent confidence interval 10 to 10

Successful Execution

Capture Matrix of the tiger capture data analysed above:

Tiger	Occasions					
	1	2	3	4	5	6
1	1	0	0	1	0	1
2	1	0	1	0	0	1
3	0	1	0	1	1	0
4	1	0	0	0	1	0
5	1	0	1	0	1	0
6	1	0	1	1	0	1
7	0	0	1	0	1	0
8	1	0	1	1	0	1
9	0	1	0	1	0	1
10	1	0	1	0	0	1

(VI) Analysis

- Every tiger captured was given a unique identification number viz. (MT-002), after examining stripe pattern on flanks, limbs, forequarters
- Following tiger identification, capture histories (X matrix) were developed and analyzed using the program MARK, CAPTURE and CARE.
- CAPTURE gives various probabilities models of the underlying capture-recapture process, that are likely to have generated the observed capture histories
- Analysis of capture history involves comparison between competing models using a series of hypothesis tests and results of an overall discriminant function test, in order to select the most appropriate abundance estimation model
- Assumption: sampled population was demographically and geographically closed during the sampling period
- Since the entire tiger reserve is camera trapped the total population within the reserve is estimated. Also the same area is camera trapped in consecutive years therefore the population is directly comparable and there is no need to compute density of tigers which adds variability and loss of precision to detect trends.

* Animal species to be recorded: tiger, fishing cat, jackal, monitor lizard, crocodile, chital, wild pig, rhesus macaque, humans and others.

^ Sign types to be recorded are pugmark/hoof mark/foot print, scat/pellet (with condition), vocalization and direct sighting.

Data sheet 1 ctd...

1) Has any tigress with cubs been reported during the past 12 months?

Yes ___ No ___ Approximate date/month _____

a) Seen by staff,

b) Pug Marks,

c) Reported by local persons,

d) Seen by officials (√ the appropriate)

How many cubs _____, approximate age of cubs _____.

2) In case tigers are known to be present in the beat, but no sign was obtained during the sampling period then mention on what evidence was this conclusion made (pugmark, direct sighting, scat, other sign) _____.

Approximate date/month _____ Tiger presence was last recorded in the beat.

3) How many livestock predation events have been recorded in the past 3 months, _____ by tigers, which carnivores if known _____, _____, _____.

4) GPS Coordinates at all creek/channel junctions in serial order of survey
